摘要: 发现心叶合耳菊(*Synotis cordifolia* Y. L. Chen)(菊科-千里光族)的模式标本与早已处理为红缨合耳菊 [*S. erythropappa* (Bureau & Franch.) C. Jeffrey & Y. L. Chen] (该种形态极为多变)的异名的 *Vernonia mairei* H. Lév. 的模式标本都采自云南东川, 在形态上没有本质区别, 故将心叶合耳菊也处理为红缨合耳菊的异名。

The Identity of *Synotis cordifolia* (Asteraceae-Senecioneae)

TANG Ming^{1,2}, WANG Long-yuan¹, YANG Qin-er^{1*}

(1. Key Laboratory of Plant Resources Conservation and Sustainable Utilization, South China Botanical Garden, Chinese Academy of Sciences, Guangzhou 510650, China; 2. University of Chinese Academy of Sciences, Beijing 100049, China)

Abstract: The type material of *Synotis cordifolia* Y. L. Chen (Asteraceae-Senecioneae) is found to match perfectly with that of *Vernonia mairei* H. Lév., which has long been treated as a synonym of the very variable *S. erythropappa* (Bureau & Franch.) C. Jeffrey & Y. L. Chen. *Synotis cordifolia* is therefore also reduced to the synonymy of *S. erythropappa*.

Key words: Asteraceae; Senecioneae; *Synotis*; Taxonomy

Synotis (C. B. Clarke) C. Jeffrey & Y. L. Chen (Asteraceae-Senecioneae) is a genus segregated from the quite heterogeneous *Senecio* L. and includes about 54 species^[1]. All the species are endemic to the Sino-Himalayan region except for the single species *S. atractylidifolia* (Ling) C. Jeffrey & Y. L. Chen, which occurs in Helan Shan, northern China^[2]. About 43 species are currently recognized from China for the genus^[1,3].

Synotis cordifolia Y. L. Chen was described based on a collection, Shun-bin Lan 307 (PE) (Fig. 1: A, B) from Dongchuan, northeastern Yunnan, China^[4]. In the protologue, the author stated that this

species is very similar to *S. erythropappa* (Bureau & Franch.) C. Jeffrey & Y. L. Chen, but differs in the leaves subleathery, cordate, margin irregularly coarsely dentate, and abaxially yellow pubescent. *Synotis cordifolia* has been recognized by Chen^[3], Liu^[5], and Chen et al.^[1]. It is noteworthy that Liu^[5] largely extended its geographical distribution by referring some northwestern and southern Yunnan collections to the species, although he felt somewhat puzzled as to why these specimens did not match well with the original description of *S. cordifolia* in some important morphological characters, such as the number of phyllaries and florets, and the pubescence

of phyllaries: these specimens often have 5 phyllaries and also 5 florets, and the phyllaries are glandular hairy outside, whereas *S. cordifolia*, according to Chen^[4], should have only 3 phyllaries and 3 florets, and the phyllaries are glabrous outside.

Synotis erythropappa is widely distributed in China and has been documented to occur in northern Guizhou (Yinjiang), western Hubei (Zigui), western Sichuan, southeastern Xizang, and northeastern and northwestern Yunnan, with the main distribution area in Sichuan and Yunnan^[1-3,5-6]. As noted by Jeffery and Chen^[2] and Chen^[3], it is a very variable species, particularly in leaf shape. Several species with various leaf shapes described from Yunnan and Sichuan, including *Senecio dianthus* Franch., *S. glumaceus* Dunn, *S. paucinervis* Dunn, *S. talongensis* Franch., *S. viridiflavus* Hand.-Mazz., and *Vernonia mairei* H. Lév., all have been placed in synonymy under *Synotis erythropappa* by Jeffery and Chen^[2]. This treatment has been widely accepted^[1,3,5-6]. Of these synonyms, *V. mairei* is worthy of special attention because its type collection, Maire s.n. (E) (Fig. 1: C), was made from Tong-Tchouan (= Dongchuan), northeastern Yunnan, which is also the type locality of *Synotis cordifolia*. The type specimen of *V. mairei* was first determined by Gagnepain^[7] as *Senecio dianthus* and later as *S. glumaceus* by Lauener^[8], both of which are synonyms of *Synotis erythropappa* as just mentioned above.

Our careful examination of the type material of *Synotis cordifolia* and *Vernonia mairei* has shown that all the specimens match perfectly with each other and definitely belong to the same entity. The leaves are long petiolate, ovate-cordate or cordate, margin irregularly coarsely dentate, abaxially yellow pubescent on veins; the phyllaries are 3 in number, glabrous outside; the florets are 3 in number, glabrous; the pappus is pale reddish. We have also checked the type material of all the other above-mentioned synonyms of *S. erythropappa* (Figs. 1: D, 2: A-D) and a large number of other specimens of the species (see below), and found that the variation of leaf shape in this species is remarkably intergrading and is not closely correlated with geographical distribution.

Plants with cordate or subcordate leaves have been discovered from various localities in western Sichuan (Luding, Maoxian) and northeastern Yunnan (Dongchuan). We therefore agree with Jeffery and Chen^[2] to treat *S. erythropappa* as a polymorphic species. Clearly, *S. cordifolia* is within the variation range of *S. erythropappa* and should be synonymized.

Those above-mentioned specimens (Fig. 3) from northwestern and southern Yunnan, which have cordate leaves and thus have been previously referred to as *Synotis cordifolia* by Liu^[5], actually belong to *S. alata* (Wall. ex DC.) C. Jeffrey & Y. L. Chen, a species within *Synotis* ser. *Synotis*. *Synotis alata* may be only distantly related to *S. erythropappa* which belongs to *Synotis* ser. *Oligantha* C. Jeffrey & Y. L. Chen. *Synotis alata* has 4–5 phyllaries usually densely setulose outside while *S. erythropappa* has 2–3(–4) phyllaries sometimes white-tomentose or pubescent, especially at the base, or glabrous (Fig. 4; also see Jeffrey and Chen^[2]). Undoubtedly the resemblance in their leaf shape is superficial. It is not surprising that Liu^[5] observed some obvious discrepancies between the specimens he examined and the original description of *S. cordifolia*.

Chen^[2], Chen^[3], and Chen et al.^[1]

Distribution and habitat. *Synotis erythropappa* is endemic to China, being documented to be widely distributed in northern Guizhou, western Hubei, western Sichuan, southeastern Xizang (Tibet), and northeastern and northwestern Yunnan (Fig. 5). It grows in forest and thicket margins, and open grassy places, at altitudes between 1500 m and 3900 m above sea level. Its occurrence in northern Guizhou (Yinjiang) reported by Chen and Liu^[6], however, needs further confirmation, because afterwards Chen^[3] and Chen et al.^[1] did not mention again any Guizhou locality for *S. erythropappa*, and we were not able to find any specimen of this species from Guizhou in the major Chinese herbaria. The only Hubei locality, Zigui, is some 800 km apart from the main distribution area, and is vouchered only by a single collection (T. P. Wang 12048, PE) with only one specimen sheet, and thus also needs further confirmation by field work.

Additional specimens examined. China:
